

Vaccine Eligibility Confirmation

The SafePaths card are distributed by the local government or employers. These cards contain one initial digitally-signed coupon QR code which would serve as proof of vaccination eligibility for an individual

2

Vaccine Administration

Post-vaccination, the clinic creates a digitally-signed immunization certificate and prints it as a badge QR sticker which contains vaccine information. Another Passkey QR sticker is also created and printed by the clinic to encrypt the badge sticker

3

Record Keeping & 2nd Dose

User records could be linked by anonymized upload to centralized systems such as VAMS. Once user receives their second vaccination dose, the clinic will create a fourth status QR sticker which will only contain information on vaccination status for future verification

Card Protocol Flow

6

Trust & Communication

Digitally-signed QR codes may be convenient and non-intrusive for users seeking vaccination. QR codes also enable verification of authentically created immunization records. Information is stored physically on a user's SafePaths card in a decentralized manner. The card enables the extension of protocols to low-resource areas to equalize disparities.

5

Safety & Efficacy Monitoring

Monitoring of health outcomes post-vaccination would follow a self-reporting scheme. This could be done by anonymized uploads to current government systems. PathCheck's scanner app could also be used to anonymously upload vaccine data and symptom reporting data to health officials and vaccine makers

4

Vaccine Verification

The status QR sticker would be scanned at venues such as airports or other public spaces to confirm an individual's vaccination status. Users could choose to allow a venue to scan the badge QR sticker using the Passkey QR sticker to provide personal information for identity verification
